Empowering Real Discoveries

Whole blood DNA extraction from PAXgene™ Blood DNA Tube using GenFind V3

This method is applicable to scientists that need to extract whole blood collected and stored in PAXgene™ Blood DNA tubes. Please reference current GenFind V3 IFU for product information (Part Number: C34880, C34881)

Purpose

The extraction of DNA from whole blood samples is critical for disease prediction and diagnosis. The PAXgene™ Blood DNA Tube is intended for the collection and stabilization of whole blood for genomic DNA (gDNA) isolation. Typically, before gDNA purification, scientists need to centrifuge the whole blood specimens to pellet down the cells and remove the liquid. This centrifuge step can be labor intensive and increase hands-on time. Here we show that the GenFind V3 protocol can process whole blood directly from PAXgene™ Blood DNA Tubes with no centrifugation step necessary.

Protocol

1. Lysis
   a. Mix by inverting the PAXgene™ Blood DNA Tube 10 times
   b. Transfer 200 µL of sample to a 2mL 96-well plate
   c. Add 500 µL of Lysis (LBB) to plate
   d. Mix by pipetting up and down 10 times, or until thoroughly mixed.
   e. Incubate the plate for 10 minutes at 37°C

2. Bind
   a. Vortex the bottle of Bind (BBB) to fully resuspend the beads
   b. Add 300 µL of Bind (BBB) to the plate
   c. Incubate the plate for 5 minutes at room temperature
   d. Place the plate on a magnet for 15 minutes (or until supernatant is clear)
   e. Remove and discard the supernatant without disrupting the beads
   f. Remove the plate from the magnet
3. Wash
   a. Add 800 µL of Wash (WBB) to plate
   b. Mix by pipetting up and down 10 times, or until thoroughly mixed
   c. Place the plate on a magnet for 10 minutes (or until supernatant is clear)
   d. Remove and discard the supernatant without disrupting the beads
   e. Remove the plate from the magnet
   f. Repeat steps 3.a-3.e for a total of 2 washes
   g. Add 1.6 mL of Wash (WBC) to plate
   h. Mix by pipetting up and down 10 times, or until thoroughly mixed
   i. Place the plate on a magnet for 10 minutes (or until supernatant is clear)
   j. Remove and discard the supernatant without disrupting the beads
   k. Remove the plate from the magnet
   l. Repeat steps 3.g-3.k for a total of 2 washes

4. Elute
   a. Add 200 µL of nuclease-free water to plate
   b. Incubate the plate for 2 minutes at room temperature
   c. Place the plate on a magnet for 2 minutes (or until supernatant is clear)
   d. Remove and Save the supernatant without disrupting the beads

Example Data
Genomic DNA extraction from blood collected in PaxGene DNA tubes

Genomic DNA (gDNA) was extracted from blood collected in PaxGene DNA tubes that were stored at 4°C for 12 days. The DNA concentration and purity were evaluated using a NanoDrop (Thermo Fisher Scientific). Three healthy donors were used to test the variability between different donors. Donors A and B had very similar DNA yields averaging 3.4 µg with concentrations averaging 34.3 ng/µL; while donor C averaged almost twice the DNA yield at 5.5 µg with a concentration of 55.6 ng/µL. This difference in yield is most likely due to inherent biological variation among donors and not due to technical or kit variation. Although there is variation in the yield among the three donors, the purity as measured by A260/280 and A260/230 absorbance ratios was consistent between all three donors. The average A260/280 absorbance ratio was 1.8, and the average A260/230 absorbance ratio was 2.2, which are within acceptable ratios as indicated by ThermoScientific T042-Technical Bulletin.
